BACKGROUND

“Smarter departures, smoother journeys - shift by 15 minutes, skip 2 hours stuck.”

CityFlow AI is a proactive traffic-management system that prevents congestion before it forms, by recommending the best time (and sometimes mode) for a person to start their journey.

Explanation: Most traffic apps are reactive - they wait for a jam to appear, then reroute you around it. But rerouting just pushes the same crowd onto a different road, which then jams too. CityFlow AI is proactive - it looks at how many people are about to travel and spreads their departure times out, so the jam never forms in the first place.

Working: The app learns your routine (office hours, gym, etc). Every day it checks predicted traffic, weather, and road conditions, then tells you the best time to leave. Example: If 10,000 people in a city normally leave from office between 6:00–6:15 PM, CityFlow AI nudges a portion of them to leave at 5:55 or 6:25 instead - same total people, same roads, but no pile-up at one instant.

TRAFFIC CONGESTION: THE REAL COST

Traffic Doesn't Just Waste Fuel - It Wastes Time

2025 traffic data shows the scale of the problem:

🚗 168 hours/year

Time lost to rush-hour traffic by an average Bengaluru commuter

🚗 152 hours/year
Pune

🚗 126 hours/year
Mumbai

🚗 104 hours/year
New Delhi

TomTom's 2025 Traffic Index reports these annual rush-hour time losses for major Indian cities.

💰 The Economic Cost is Also Huge

₹11.7 billion (~₹1,170 crore)

Estimated monetary cost of **7.07 lakh** productive hours lost due to traffic-related late arrivals in Bengaluru (2018 estimate cited in India's Economic Survey 2025–26).

USD 22 billion/year

Estimated congestion-related cost across Delhi, Mumbai, Bengaluru and Kolkata in a 2018 Uber–BCG estimate cited by the Economic Survey.

The Problem

Every hour lost in traffic is time that could have been spent working, studying, resting, or with family.

CityFlow AI's Goal

Prevent peak congestion before commuters get stuck - so the same journey takes less time and creates less cumulative loss.

Sources: TomTom Traffic Index 2025; Government of India, Economic Survey 2025–26.

LITERATURE REVIEW

<u>Existing Approach</u>	<u>What It Does</u>	<u>Limitation / Gap</u>
Google Maps / Waze	Reroutes users based on current traffic	Mainly reactive after congestion develops
Traffic Signal Optimization	Adjusts signal timings to reduce congestion	Addresses traffic at intersections rather than departure demand
Traffic Prediction Models	Predict future traffic conditions	Usually predicts congestion but does not directly coordinate commuter departure times

Research Gap:

Existing Approach:

Traffic forms →
Commuters get stuck →
Reroute / Signal Control

CityFlow AI:

Predict demand →
Stagger departures →
Prevent peak overload
Instead of managing traffic after people are stuck, CityFlow AI works one step earlier - preventing too many vehicles from entering the network at the same time.

PROBLEM STATEMENT

Every evening, in almost every large Indian city, the same thing happens. Offices close within a narrow time window, and thousands of people begin their commute at nearly **the same time**. The roads have not suddenly become smaller, and the number of vehicles has not suddenly multiplied. The problem is that **too many vehicles enter the network at the same time**.

The Real Impact

A typical office-to-home journey may take only **15–20** minutes under normal traffic conditions. During peak hours, the same journey can stretch to **1–2+** hours because thousands of commuters enter the road network simultaneously.

So the challenge is **not simply distance** - it is **synchronized demand**.

PROBLEM STATEMENT

The Current Problem

- Existing solutions such as Google Maps, Waze, and city traffic-signal systems primarily respond to congestion after it begins.
- They reroute vehicles or adjust signal timings to reduce congestion on affected roads.
- These approaches are useful, but largely reactive - rerouting can shift the same traffic pressure to another road rather than preventing the initial overload.

The Gap

Current systems ask:

“Which road should this vehicle take?”

CityFlow AI asks:

“How can we prevent too many vehicles from entering the road network at the same time?”

The goal is to move from reactive congestion management to proactive traffic prevention.

OBJECTIVE : DEMAND SMOOTHING

Goal: Spread the same number of trips across a wider time band to prevent short periods of extreme demand.

How It Works

1. Forecast Demand
2. Predict traffic demand for each area and time slot.
3. Identify Peak Windows
4. Detect time slots where vehicle demand is likely to exceed road capacity.
5. Generate Staggered Departures
6. Calculate recommended departure times while considering the commuter's desired arrival time.
7. Smooth the Demand
8. Distribute trips across a wider window so that no single 15-minute period becomes overloaded.

Example

Without CityFlow AI

6:00 PM → 🚗🚗🚗🚗🚗🚗🚗🚗

With CityFlow AI

5:45 → 🚗🚗 | 6:00 → 🚗🚗 | 6:20 → 🚗🚗 | 6:30 → 🚗🚗

Same trips. Better distribution. Less peak overload.

SCOPE

CityFlow AI is developed as a working prototype and evaluated on a **simulated urban environment** using SUMO, rather than deployed on a live city network.

Core Feature

- Departure-Time Optimizer - predicts demand and recommends staggered departure times to smooth peak traffic.

Supporting Features

- Road-Condition Detection - detects potential potholes and road-surface anomalies using smartphone sensors.
- Carpool Matching - connects commuters with compatible routes and schedules.
- Multi-Modal Suggestions - recommends bus, metro, or cycling options for commuters with fixed schedules.
- Explainable Recommendations - provides a clear reason behind every suggested departure time or travel option.

Evaluation Environment

Simulated City → SUMO Traffic Simulation → CityFlow AI → Optimized Demand & Travel

DATASET & RESOURCE PLANNING

Data Sources

Traffic / Mobility Data

- Vehicle count, speed, travel time and congestion patterns
- Used for demand forecasting and SUMO evaluation

Road Network Data

- OpenStreetMap road-network data
- Used to create the simulated city

Public Transport Data

- GTFS routes and schedules
- Used for multi-modal suggestions

Road-Condition Data

- Smartphone accelerometer/gyroscope readings
- Used to detect road impacts and estimate road health

User Routine Data

- Typical departure time, destination and travel preferences
- Used for personalized recommendations

Resources

- Hardware: Smartphone + Laptop/Desktop
- Simulation: SUMO + OpenStreetMap
- Backend: FastAPI + PostgreSQL + Redis
- AI/ML: Prophet / XGBoost / LSTM/TFT
- Optimization: OR-Tools

HARDWARE & SOFTWARE REQUIREMENTS

Hardware

- **Smartphone** - GPS + accelerometer/gyroscope for demonstrating road-condition detection and routine tracking; no additional hardware required.
- **Laptop/Desktop** - development, simulation, testing, and project demonstration.

Software Requirements

- **Frontend:** HTML5, CSS3, JavaScript, React/Flutter, Leaflet, OpenStreetMap, Chart.js/Recharts — builds the commuter app, maps, and planner dashboard.
- **Backend & Database:** FastAPI, PostgreSQL, Redis - handles APIs, data storage, caching, and background tasks.
- **Simulation:** SUMO, OpenStreetMap - simulates the city road network for testing and evaluation.
- **AI/ML:** Prophet, XGBoost, LSTM/TFT - forecasts traffic demand and identifies future congestion patterns.
- **Optimization:** Google OR-Tools, Graph-based & Multi-Agent Optimization - generates optimal, staggered departure schedules.
- **Road Detection:** DeviceMotion API, Weighted Road-Health Scoring - detects road anomalies and estimates road condition.
- **Conversational Input:** Free-tier LLM API - understands natural-language schedule changes from commuters.
- **Deployment & Testing:** Docker, GTFS, Automated Testing, CI/CD - supports deployment, transit integration, and system reliability.
- **Privacy:** k-Anonymity-style Data Bucketing - protects commuter location data before storage.

HOW CITYFLOW AI WORKS

PART 1: DEPARTURE-TIME OPTIMIZATION

STEP 1 : USER SETS THEIR ROUTINE

THE COMMUTER ENTERS:

HOME → OFFICE
USUAL DEPARTURE
TIME → 9:00 AM
REQUIRED ARRIVAL
TIME → 9:30 AM

THE SYSTEM LEARNS
THE USER'S REGULAR
TRAVEL PATTERN.

STEP 2 : COLLECT CITY & TRAFFIC DATA

CITYFLOW AI USES:

- TRAFFIC / VEHICLE-FLOW DATA
- ROAD-NETWORK DATA FROM OPENSTREETMAP
- WEATHER / EVENT INFORMATION
- PUBLIC-TRANSPORT DATA WHERE REQUIRED
- USER TRAVEL PATTERNS

THIS DATA TELLS THE SYSTEM WHO IS TRAVELLING, WHERE THEY ARE TRAVELLING AND WHEN DEMAND IS INCREASING.

STEP 3 : FORECAST FUTURE DEMAND

THE AI/ML MODEL PREDICTS THE EXPECTED TRAFFIC DEMAND FOR EACH AREA AND TIME SLOT.

TIMEPREDICTED DEMAND

8:45 AM

● LOW

9:00 AM

● VERY HIGH

9:15 AM

● MEDIUM

THE AIM IS TO IDENTIFY WHEN THE ROAD NETWORK IS LIKELY TO BECOME OVERLOADED.

STEP 4 : DEPARTURE-TIME OPTIMIZER

THE PREDICTED DEMAND IS GIVEN TO THE DEPARTURE-TIME OPTIMIZER.

USING GOOGLE OR-TOOLS, THE SYSTEM CHECKS POSSIBLE DEPARTURE TIMES AND **FINDS A SCHEDULE THAT:**

- REDUCES PEAK OVERLOAD
- KEEPS COMMUTERS WITHIN THEIR ACCEPTABLE ARRIVAL WINDOW
- SPREADS VEHICLES ACROSS NEARBY TIME SLOTS

EXAMPLE

INSTEAD OF:

1,000 PEOPLE → LEAVE AT 9:00 AM

THE SYSTEM MAY RECOMMEND:

300 → 8:45 AM

400 → 9:00 AM

300 → 9:15 AM

SO THE SAME NUMBER OF TRIPS ARE SPREAD OVER A WIDER TIME PERIOD.

RESULT

FEWER VEHICLES ENTER THE NETWORK AT THE SAME MOMENT → PEAK CONGESTION IS REDUCED → COMMUTERS EXPERIENCE LESS DELAY.

HOW WE TEST THE IDEA : SUMO SIMULATION

WE CREATE A SIMULATED CITY USING SUMO
OPENSTREETMAP

→ PROVIDES THE ROAD-NETWORK STRUCTURE

SUMO (SIMULATION OF URBAN MOBILITY)

→ CREATES A SIMULATED TRAFFIC ENVIRONMENT

BASELINE SCENARIO

EVERYONE FOLLOWS THEIR NORMAL DEPARTURE TIME.

EXAMPLE: MOST COMMUTERS LEAVE AT 9:00 AM

WE RECORD:

- TRAVEL TIME
- TRAFFIC CONGESTION
- VEHICLE FLOW
- WAITING/DELAY

CITYFLOW AI SCENARIO

THE SAME SIMULATED COMMUTERS RECEIVE STAGGERED DEPARTURE TIMES FROM OUR OPTIMIZER.

FOR EXAMPLE:

8:45 → 9:00 → 9:15 → 9:30

WE RUN THE SIMULATION AGAIN.

COMPARE BOTH RESULTS WITHOUT CITYFLOW AI

- HIGH PEAK CONGESTION
- HIGHER TRAVEL TIME
- MORE WAITING

WITH CITYFLOW AI

- SMOOTHER VEHICLE FLOW
- LOWER PEAK CONGESTION
- REDUCED TRAVEL DELAY

OUR EVALUATION

BASELINE VS. CITYFLOW AI

WE COMPARE THE RESULTS TO MEASURE WHETHER DEMAND SMOOTHING ACTUALLY REDUCES CONGESTION AND TRAVEL TIME.

CITYFLOW AI DOES NOT WAIT FOR COMMUTERS TO GET STUCK IN TRAFFIC – IT ACTS BEFORE THE PEAK FORMS.

PART 2: AUTOMATIC POTHOLE DETECTION

1. SMARTPHONE SENSORS

THE COMMUTER'S PHONE USES: ACCELEROMETER + GYROSCOPE TO DETECT UNUSUAL MOVEMENTS OR JOLTS WHILE TRAVELLING.

2. DETECT ROAD IMPACT

IF THE PHONE DETECTS A STRONG AND UNUSUAL VERTICAL/VEHICLE MOVEMENT, THE SYSTEM IDENTIFIES IT AS A POSSIBLE POTHOLE/ROAD IMPACT.

3. MULTIPLE USERS CONFIRM THE LOCATION

THE SYSTEM COLLECTS REPEATED DETECTIONS FROM DIFFERENT VEHICLES TRAVELLING THROUGH THE SAME ROAD SEGMENT. FOR EXAMPLE:
SECTOR 12 ROAD → 340 DETECTED IMPACTS

4. THRESHOLD-BASED PRIORITY

A THRESHOLD IS APPLIED TO DISTINGUISH ISOLATED NOISE FROM REPEATED ROAD-CONDITION SIGNALS.

BELOW THRESHOLD → LOW PRIORITY

ABOVE THRESHOLD → HIGHER CONFIDENCE / PRIORITY
THE MORE REPEATED DETECTIONS A ROAD RECEIVES, THE MORE IMPORTANT IT BECOMES FOR INSPECTION.

5. MUNICIPAL DASHBOARD

THE DETECTED ROAD CONDITION APPEARS ON YOUR MUNICIPAL CORPORATION DASHBOARD PROTOTYPE.

MUNICIPAL OFFICIALS CAN SEE:

ROAD → NUMBER OF DETECTIONS
→ PRIORITY
AND IDENTIFY WHICH ROADS NEED ATTENTION FIRST.

CURRENT PROTOTYPE VS FUTURE GOVERNMENT SYSTEM

CURRENT CAPSTONE PROTOTYPE:

THE DETECTION IS DEMONSTRATED THROUGH OUR SIMULATED/IMPLEMENTED MUNICIPAL PORTAL.

FUTURE GOVERNMENT DEPLOYMENT:

AFTER GOVERNMENT APPROVAL AND INTEGRATION, THESE AUTOMATICALLY GENERATED ROAD-CONDITION REPORTS COULD BE CONNECTED TO THE ACTUAL MUNICIPAL SYSTEM.

PART 3: TRUST, PARTICIPATION & REWARDS

1. USER TRUST

CITYFLOW AI PROVIDES:

- ANONYMOUS LOGIN
- MINIMAL PERSONAL-DATA COLLECTION
- PRIVACY-PRESERVING LOCATION HANDLING
- EXPLANATION FOR EVERY RECOMMENDATION

THE USER SHOULD KNOW WHAT DATA IS BEING USED AND WHY.

2. WHY WOULD USERS PARTICIPATE?

SUPPOSE THE APP TELLS A COMMUTER:

“LEAVE 15 MINUTES EARLIER TO AVOID THE PREDICTED PEAK.”

INSTEAD OF MAKING IT FEEL LIKE AN INSTRUCTION, THE SYSTEM PROVIDES AN INCENTIVE:

FOLLOW RECOMMENDATION → EARN REWARD POINTS / ELIGIBLE BENEFITS

POSSIBLE FUTURE BENEFITS:

- FUEL BENEFITS
- PARTNER DISCOUNTS
- PUBLIC-TRANSPORT BENEFITS
- OTHER GOVERNMENT-APPROVED MOBILITY INCENTIVES

3. WHY WOULD THE GOVERNMENT SUPPORT IT?

TRAFFIC CONGESTION CREATES A LARGE CUMULATIVE LOSS OF TIME, FUEL AND PRODUCTIVITY.

IF CITYFLOW AI REDUCES UNNECESSARY PEAK CONGESTION, THE RESULTING SOCIETAL/ECONOMIC BENEFIT CAN JUSTIFY **GOVERNMENT INVESTMENT AND INCENTIVE PROGRAMMES.**

GOVERNMENT-BACKED MODEL

GOVERNMENT INVESTMENT → USER INCENTIVES → HIGHER PARTICIPATION → MORE STAGGERED TRIPS → LOWER PEAK CONGESTION → LESS TIME/FUEL/PRODUCTIVITY LOST

4. ORGANISATIONS CAN PARTICIPATE

COMPANIES CAN VOLUNTARILY:

STAGGER EMPLOYEE SHIFT TIMINGS INSTEAD OF HAVING EVERYONE LEAVE AT THE SAME TIME.

THEY CAN ALSO PARTICIPATE IN FUTURE INCENTIVE/BENEFIT PROGRAMMES.

TRUST & PARTICIPATION

User Privacy

- **Anonymous login**
- Minimal personal data collection
- Privacy-preserving location handling
- Users can see why a recommendation is made

User Participation

- Users voluntarily follow recommended departure times
- Earn **reward** points / eligible **benefits** for participation

Government & Organisation Participation

- Government can provide **the policy framework and incentives**
- Organisations can voluntarily adopt staggered work/shift timings
- Possible incentives: **fuel benefits, tax/fee incentives, public-transport benefits or partner discounts**

Why would users participate?

“**If shifting your departure by 15 minutes can help you avoid 2 hours of traffic** - and you also receive a benefit for participating - there is a reason to follow the recommendation.”

SYSTEM ARCHITECTURE & PROCESS FLOW

Our system works in 5 simple layers:

Input → Processing → Support → Delivery → Application.

1. Input Layer : Collects Data

The system collects:

- **User data** - daily routine and travel preferences from the phone.
- **City data** - traffic, weather, and events.
- **Road data** - automatically detected road impacts using smartphone accelerometer/gyroscope sensors.

2. Processing Layer : Understands the Situation

- Demand Forecasting predicts where and when traffic will increase.
- Road-Condition Module checks the condition of different roads.
- Departure-Time Optimizer combines this information and decides the best time for people to leave.

3. Support Layer : Improves the Recommendation

- Carpool Module checks whether people can share a ride.
- Multi-Modal Module suggests options like bus, metro, or bike.
- Data Layer stores and retrieves all the required information.

4. Delivery Layer : Explains the Decision

The system converts the final result into a simple recommendation with a clear reason.

5. Application Layer : Shows the Result

- Commuter App shows users **when they should leave**, so they will not encounter any traffic and which option is better.
- City Planner Dashboard shows traffic congestion and road conditions to planners.

Example

A commuter normally leaves at **9:00 AM**.

The system predicts that leaving at 9:00 AM could put the commuter into heavy peak-hour traffic, potentially causing a much longer journey.

Instead of getting stuck in traffic for **1–2 hours**, the system recommends:

“Leave at **8:45 AM** instead - avoid the peak congestion and reach your destination more reliably.”

15 minutes earlier is better than losing 1–2 hours in traffic.

ARCHITECTURE DIAGRAM

★ **KEY BENEFIT** Tells you when to leave → Avoid peak-hour traffic & bad roads → Save 1–2 hours every day = **Smarter commute. Better cities.**

Project Timeline

Phase	Timeline	Team Activity
Review 0	03–08 Aug 2026	Idea finalization & problem identification
Review 1	03 - 08 Sept 2026	Background study, literature review, objectives, dataset & resource planning, proposed methodology
Development	Sep 2026	Model development, backend/frontend integration & SUMO simulation
Testing & Evaluation	Sep–Oct 2026	Testing, optimization, performance evaluation & result analysis
Review 2	28 Sep–06 Oct 2026	Working prototype, testing & results demonstration
Final Phase	Oct–Nov 2026	Refinement, documentation & final presentation

USABILITY & APPLICATIONS

Everyday Commuters

Who: Working professionals and daily commuters.

How it helps:

Provides personalized departure-time and travel recommendations based on predicted traffic and road conditions.

Example:

“Leave at 8:45 instead of 9:00 - avoid the peak traffic and reach more reliably.”

Benefit: Save up to 1–2 hours otherwise wasted in traffic and use that time for more productive or personal activities.

Municipal Corporations

Who: City authorities and road-maintenance departments.

How it helps:

Uses automatically detected road-condition data to identify and prioritize damaged road segments.

Example:

“Sector 12 Main Road — high number of detected road impacts this week → High Priority.”

Benefit: Helps authorities identify problem roads faster without depending only on manual complaints.

Organisations

Who: Companies managing employee commute and shift timings.

How it helps:

Uses aggregated commute patterns to identify peak travel periods and evaluate staggered shift timings.

Example:

“Shifting a portion of employees by 15 minutes could reduce peak-hour demand.”

Benefit: Helps reduce commute delays, improve employee productivity, and potentially lower travel-related emissions.

CONTRIBUTION OF EACH MEMBER

<u>Member</u>	<u>Contribution / Responsibility</u>
Shreya Goyal	System Architecture, FastAPI Integration, Pothole Detection & SUMO Simulation ,UI/UX Design — designed the user interface, worked with backend APIs, road-condition detection, and simulation setup.
Shansit Suman	Departure-Time Optimization & Backend Logic — developed the core departure-time scheduling logic and backend processing for demand-based recommendations.
Samarth Singh	Privacy & Security of users data — worked on anonymous login, data protection, and privacy-preserving handling of commuter data.
Tithi Semwal	Municipal Corporation Dashboard — designed the planner/municipal interface for viewing congestion, road-health information, and prioritized road issues.
Shashank Dubey	Artificial Intelligence/Machine Learning & Demand Forecasting — worked on traffic-demand prediction, model selection, data preprocessing, and forecasting workflow.
Bhavya Agrawal	Testing, Rewards/Gamification, Documentation & Integration — handled test planning, documentation, system integration, and Worked on reward points for commuter participation & organisations.
